The central chapter discusses how ordering concepts can be applied to block designs, with definitions from existing (configuration orderings) and new (Gray codes and universal cycles for designs) research. Two chapters are devoted to a survey of results in the field, including illustrative proofs and examples.

The reflected binary code or Gray code is an ordering of the binary numeral system such that two successive values differ in only one bit (binary digit). Gray codes are very useful in the normal sequence of binary numbers generated by the hardware that may cause an error or ambiguity during the transition from one number to the next.

Gray code encoders, also known as reflected binary code encoders, produce only a single bit change at each step, which can reduce encoder communication errors. Gray code encoders are an option for serial or parallel encoder communication protocols. Learn more and browse popular gray scale encoders!

Gray code generator and decoder Carsten Kristiansen - Napier No.: 04007712 3. Assignment specifications • Use JK flip-flops and suitable logic gates to design a 4-bit binary Gray code generator. • Use the output of the Gray code generator as inputs to a combinational logic circuit to decode the Gray code to produce the normal binary counting sequence.

Gray code - also known as Cyclic Code, Reflected Binary Code (RBC), Reflected Binary (RB) or Grey code - is defined as an ordering of the binary number system such that each incremental value can only differ by one bit. In gray code, while traversing from one step to another step only one bit in the code group changes.

A Gray code represents each number in the sequence of integers {0...2^N-1} as a binary string of length N in an order such that adjacent integers have Gray code representations that differ in only one bit position. Marching through the integer sequence therefore requires flipping just one bit at a time.
